

17. READING THE SKIN

DURATION : 10:59

STUDY SHEET

COURSE SUMMARY

This video explores the essential role of the skin as a reflection of cerebrospinal fluid quality and internal imbalances. Through embryological concepts, it explains how the skin develops from the neural crest and how hormonal and metabolic imbalances can manifest through various changes in skin pigmentation and condition. The interactions between organs, such as those between the thyroid, adrenals, and circulatory system, are also discussed to offer an integrative view of treating skin problems. By understanding these interactions, therapists can better diagnose and release bodily tensions for optimal well-being.

READING THE SKIN

The **skin** is a reflection of the quality of the **cerebrospinal fluid**. During neural tube closure, the skin develops from the **neural crest**. This process begins with a neural plate, surrounded by **amniotic fluid**, which forms a neural groove. This amniotic fluid represents the primitive cerebrospinal fluid. Thus, the fluid present in the neural tube has the same origin as the surrounding tissue.

Treating the skin means re-releasing the entire cerebrospinal fluid system and promoting drainage spaces. The skin also reflects the balance of reciprocal tensions of the membranes and the lymphatic system. It is the basal expression of the deep metabolic balance of the nervous system, reflecting the body's internal quality.

An imbalance can manifest on the skin, whether through skin problems or vitamin and mineral imbalances, particularly in areas integrated with the neural crest. At the time of neural crest formation, these migrate throughout the body, especially in the face and digestive system, thus forming the peripheral neurological system.

SKIN COLOURS AND MEANINGS

Skin colour can indicate various health states:

- **Tan:** Increased melanin. Be careful with excessive exposure.
- **Brown colour:** May indicate an imbalance, such as **Addison's disease**.
- **Yellow colour:** May signal liver or biliary damage.
- **Black skin:** May reflect a deep disorder at the pancreatic level.
- **Straw colour:** Suspicion of future cancer.

Hormones, particularly those related to pregnancy, also influence skin pigmentation. For example, hypothyroidism disrupts melanin, while pituitary and adrenal hormones also act on it.

ROLE OF THE THYROID AND ADRENALS

The **thyroid** works in tandem with the **adrenals**. It plays a crucial role in body oxygenation, while the adrenals help detoxify thanks to **cortisol**. The conversion of T3 to T4, essential thyroid hormones, depends on cortisol balance. Excessive stress increases cortisol, inhibiting the conversion of T3 to T4, which disrupts cellular oxygenation.

The adrenals, in addition to producing hormones, are also responsible for the production of neurotransmitters. Adrenal failure can lead to various health problems, including rhinitis, migraines, and other symptoms related to stasis.

INTERACTIONS BETWEEN ORGANS

There is a significant dynamic between the heart, liver, spleen, and small intestine. The liver, as a meeting point between different types of tissues, is influenced by adrenal function. A congested liver can manifest as a red face, indicating portal hypertension or excess iron storage.

Skin colours can also indicate imbalances:

- **Red:** May signal thyroid dysfunction or portal hypertension.
- **Dull, grey, brown:** Indicates melanin deposits and a physiological imbalance.
- **Blue:** May express a cardiovascular imbalance or poor oxygen absorption.

CONCLUSION

The skin is a valuable indicator of internal health. Hormonal imbalances, particularly those related to the thyroid, can manifest as skin changes. It is essential to consider the entire system, including interactions between organs, to understand and treat skin problems.
