

28. EMBRYOLOGICAL RECONNECTION REMINDER

DURATION : 03:13

STUDY SHEET

COURSE SUMMARY

This video explores embryological reconnection, a fundamental concept in biodynamic embryology and osteopathy. The speakers discuss the development of organs such as the peritoneum and spleen, as well as their ability to regain ontogenetic functions. Participants learn how essential components such as trajectory, metabolic concentration, and intercellular substances interact to form vessels, and how volumetric balance is crucial for overall health. The impact of birth compressions on blood circulation is also addressed, as well as the importance of inner silence and learning in a state of calm to foster gratitude and body reorganisation.

EMBRYOLOGICAL RECONNECTION REMINDER

Each developing **organ** at every moment achieves the best of its **potential**. Each stage of development can be considered a **function**. In an early stage, the **peritoneum** expressed an osmotic membrane, which could be considered a **primitive kidney**. In some cases, the peritoneum can revert to being a **dialysis membrane**.

The peritoneum, the **spleen**, and even certain parts of the **myocardium** can re-express **ontogenetic** adaptation situations and regain functions. The spleen is particularly important in the development of the **circulatory system**. During the establishment of this system, **pressures** are created in the spleen, influencing whether certain volumes open or not.

For a **vessel** to form, four components are necessary: a **trajectory**, a **metabolic concentration**, **vacuolisation**, and the presence of **intercellular substances**. A vessel can be compared to a **rainbow**: in a given space-time, the presence of the sun, rain, and an adequate inclination are needed for it to appear. If one of these conditions disappears, the vessel also disappears.

In the **ontogenetic** process, vessels appear and then disappear, because there is a crucial **volumetric** balance between the heart, liver, spleen, and small intestine, which act as **blood sponges**, in collaboration with the **lungs**.

At the time of **birth**, there are not only bone compressions but also volumetric compressions. By compressing, blood flow is increased in certain areas, thus modifying circulation patterns.

Some people may be blocked at the level of the spleen, which is referred to as **splenic**. This can manifest mentally as **melancholic** tendencies. It is essential to release these pressure fields, as our mentality relies on volumes.

We learn in deep **silence**, often during an **expiratory apnoea**. In this state, we continuously receive information. Similarly, in the tissue, we look for **points of stillness**, because that is where the body reorganises itself.

True silence is comparable to **gratitude**: it implies gratuity and freedom. This feeling of thankfulness is what the tissue seeks. It seeks to find its point of **gratitude** to rebalance itself. The embryo perfectly illustrates this process.
